Recall $\Delta^1 = Hom(-, [1])$. $\Delta^1\times(-)$ is an exact cylinder, ie an endofunctor of the category of simplicial sets, with $(\partial_1,\partial_2):1\coprod1\to \Delta^1\times(-)$ and $\sigma:\Delta^1\times(-)\to 1$, satisfying some properties.

Definition 3.1.1.

An anodyne extension is an element of the smallest class of $\Delta^1 \times (-)$ -anodyne maps.

[Introduction and goal](#page-1-0) Definitions for our structures [First properties](#page-15-0) [Bisimplicial sets](#page-25-0) [Partially ordered sets](#page-28-0) [Teasers](#page-33-0) [Anodyne extensions](#page-5-0) Kan fibrations [The Kan-Quillen model structure](#page-13-0)

See Example 2.4.13 for the construction of this smallest class, here for $I=\Delta^1\times (-)$ and $S=\varnothing$:

1 - choose a cellular model M ;

 $2 - set$:

$$
\Lambda^0_I(S,M)=S\cup\{I\otimes K\cup\{\epsilon\}\otimes L\to I\otimes L|K\to L\in M,\epsilon=0,1\};
$$

 3 - set by induction on n :

$$
\Lambda_I^{n+1}(S,M)=\{I\otimes K\cup\partial I\otimes L\to I\otimes L|K\to L\in\Lambda_I^n(S,M)\};
$$

 $4 - set$:

$$
\Lambda_I(S,M)=\cup_{n\geq 0}\Lambda_I^n(S,M);
$$

5 - set :

$$
An(S) = I(r(\Lambda_1(S,M)))
$$

[Anodyne extensions](#page-5-0) Kan fibrations [The Kan-Quillen model structure](#page-13-0)

Proposition 3.1.2 (Gabriel and Zisman).

The following three classes of morphisms of simplicial sets are equal: (a) the class of anodyne extensions; (b) the smallest saturated class of maps containing inclusions of the form

$$
\Delta^1 \times \partial \Delta^n \cup \{\epsilon\} \times \Delta^n \to \Delta^1 \times \Delta^n \quad \text{for } n \ge 0 \text{ and } \epsilon = 0, 1;
$$

(c) the smallest saturated class containing inclusions of the form

$$
\Lambda_k^n \to \Delta^n \quad \text{for } n \ge 1 \text{ and } 0 \le k \le n.
$$

[Anodyne extensions](#page-5-0) Kan fibrations [The Kan-Quillen model structure](#page-13-0)

Proof of $(a) = (b)$.

To build $An(S)$ using our algorithm, take $M = \{ \partial \Delta^n \to \Delta^n, n \geq 0 \}.$ Goal : prove $I(r(\Lambda_1(S, M))) = I(r(\Lambda_1^0(S, M)))$. We already have the the reverse inclusion because $\Lambda_I(S,M) \supset \Lambda_I^0(S,M)$. Let's show $\Lambda_I(S,M) \subset I(r(\Lambda^0_I(S,M)))$. Actually, sufficient to prove that for any monomorphism $K \to L$ and $\epsilon = 0, 1$, the inclusion :

$\Delta^1 \times K \cup \{\epsilon\} \times L \to \Delta^1 \times L$

belongs to $\mathit{l}(\mathit{r}(\Lambda^0_I(S, M)))$. This is true for all the maps of M . And M is a cellular model, and the above property is stable under saturation, so it is true for all monomorphisms.

[Anodyne extensions](#page-5-0) Kan fibrations [The Kan-Quillen model structure](#page-13-0)

Lemma 3.1.3.

The following two classes of morphisms are equal: (a) the smallest saturated class of maps containing inclusions of the form

$$
\Delta^1 \times \partial \Delta^n \cup \{1\} \times \Delta^n \to \Delta^1 \times \Delta^n \quad \text{for } n \geq 0 \text{ and } \epsilon = 0, 1;
$$

(b) the smallest saturated class containing inclusions of the form

$$
\Lambda_k^n \to \Delta^n \quad \text{for } n \ge 1 \text{ and } 0 < k \le n.
$$

KORK EX KEY ADY AND YOUR

Definition 3.1.5.

A Kan fibration is a morphism of simplicial sets with the right lifting property with respect to the inclusions of the form $\Lambda^n_k \to \Delta^n$, for $n \geq 1$ and $0 \leq k \leq n$.

A Kan complex is a simplicial set X such that the morphism from X to the final simplicial set is a Kan fibration.

Ie :

[Anodyne extensions](#page-5-0) **Kan fibrations** [The Kan-Quillen model structure](#page-13-0)

Corollary 3.1.6.

For any monomorphism $i: U \to V$ and for any Kan fibration $p: X \to Y$, the canonical map

$$
(i^*, p_*) : \underline{\text{Hom}}(V, X) \to \underline{\text{Hom}}(U, X) \times_{\underline{\text{Hom}}(U, Y)} \underline{\text{Hom}}(V, Y)
$$

is a Kan fibration.

Corollary 3.1.7.

For any anodyne extension $i: K \rightarrow L$ and for any Kan fibration $p: X \rightarrow Y$, the canonical map

$$
(i^*, p_*) : \underline{\text{Hom}}(L, X) \to \underline{\text{Hom}}(K, X) \times_{\underline{\text{Hom}}(L, Y)} \underline{\text{Hom}}(K, Y)
$$

is a trivial fibration.

[Anodyne extensions](#page-5-0) Kan fibrations [The Kan-Quillen model structure](#page-13-0)

Theorem 3.1.8.

There is a unique model category structure on the category of simplicial sets whose class of cofibrations is the class of monomorphisms, and whose fibrant objects are the Kan complexes. Moreover, any anodyne extension is a trivial cofibration, and the fibrations between fibrant objects exactly are the Kan fibrations between Kan complexes.

Definition 3.1.9

The structure we get will be called the Kan-Quillen model category structure.

Its weak equivalences will be called the weak homotopy equivalences.

[Anodyne extensions](#page-5-0) Kan fibrations [The Kan-Quillen model structure](#page-13-0)

Proof.

The theorem 2.4.19, applied to the category of simplicial sets for Δ^1 × (–) and for An, gives us the model category structure, where :

- \bullet the cofibrations are the monomorphisms;
- weak equivalences are the morphisms $f : X \rightarrow Y$ such that, for any fibrant presheaf $\,W$, $f^*: [Y,W] \rightarrow [X,W]$ is bijective;
- **•** naive fibrations are the morphisms having the right lifting property with respect to An;
- \bullet the fibrant presheaves X are the ones such that the map from X to the final preashef is a naive fibration.

Then, use proposition 3.1.2 to rewrite An as the smallest saturated class containing the $\mathsf{\Lambda}^n_k \to \Delta^n$

Corollary 3.1.10.

The class of weak homotopy equivalences is closed under finite products.

K ロ ▶ K @ ▶ K 할 ▶ K 할 ▶ 이 할 → 9 Q @ 17 / 39

[Useful lemmas](#page-16-0) [An extension property](#page-21-0)

Proof.

Equivalent to prove that for any simplicial set Y , the functor $X \mapsto X \times Y$ preserves weak equivalences. By corollary 3.1.4 it preserves anodyne extensions. Then use proposition 2.4.40 to show it preserves trivial cofibrations. As it also preserves cofibrations, then it is part of a Quillen adjunction. And as all simplicial sets are cofibrant, then it will preserve weak equivalences.

[Useful lemmas](#page-16-0) [An extension property](#page-21-0)

Lemma 3.1.11.

Let $\mathcal C$ be a category in which a commutative square

$$
\begin{array}{ccc}\nA & \xrightarrow{i} & B \\
\downarrow{j} & & \downarrow{j} \\
C & \xrightarrow{k} & D\n\end{array}
$$

is given. Assume that the maps j, k, l have retractions r, q, p , respectively, and that $pk = ir$ Then this square is absolutely Cartesian.

KOD KAD KED KED E VAN

[Useful lemmas](#page-16-0) [An extension property](#page-21-0)

Proof.

It is sufficient to check that the square is Cartesian. If $u: X \to C$, $v: X \to B$ are such that $ku = l v$, then taking $w = ru : X \rightarrow A$ leads to $kiw = ku$ and $liw = iv$ (using the retractions), but k, l are monomorphisms, thus the existence of w. For the unicity, use the retraction of *j* : then $w = r_j w = ru$.

[Useful lemmas](#page-16-0) [An extension property](#page-21-0)

Lemma 3.1.11.

:

Let $n \geq 2$ and $0 \leq i < j \leq n$, the following square is absolutely Cartesian

K ロ ▶ K @ ▶ K 할 ▶ K 할 ▶ 이 할 → 9 Q @ 21 / 39

[Useful lemmas](#page-16-0) [An extension property](#page-21-0)

Recall (theorem 1.1.10) : extension by colimits : Given a small category D and a locally small category C which has small colimits, any functor $u: D \to C$ can be 'extended' to a functor $u_!:\hat{D}\to\mathcal{C}$, where $u_!$ is the left adjoint of the functor of evaluation at $u_!$

[Useful lemmas](#page-16-0) [An extension property](#page-21-0)

Proposition 3.1.13.

Let $\mathcal C$ be a small category and $A: \Delta \to \hat{\mathcal C}$ a functor. Then the induced colimit preserving functor $A_{!}: {\mathcal{S}}$ et $\to \hat{\mathcal{C}}$ preserves monomorphisms if and only if the map

$$
(A(\delta^1_0),A(\begin{smallmatrix}1\\ 1\end{smallmatrix})):A^0\coprod A^0\to A^1=A_!(\Delta^1)
$$

is a monomorphism.

Sketch of proof.

Recall that the class of monomorphisms of simplicial sets is the smallest saturated class containing the inclusions $\partial\Delta^{\bar n} \to \Delta^{\bar n}$. So it suffices to checks these inclusions are sent to monomorphisms. For $n = 0$: by cocontinuity of $A_!$. And for $n\geq 2$, they are always sent to a monomorphism (using last lemma).

[Useful lemmas](#page-16-0) [An extension property](#page-21-0)

24 / 39

4 ロ > 4 何 > 4 ヨ > 4 ヨ > ニヨークQC

Proposition 3.1.14.

Let $A, B: \Delta \to C$ be two functors with values in a model category. We denote by A_1 and B_1 their extensions by colimits, respectively, and we assume that both of them send monomorphisms to cofibrations. If a natural transformation $u:A\to B$ induces a weak equivalence $A^n\to B^n$ for all $n \geq 0$, then, for any simplicial set X, the map

$$
u_X: A_!(X) \to B_!(X)
$$

is a weak equivalence.

[Useful lemmas](#page-16-0) [An extension property](#page-21-0)

Proof.

Consider the class of X such that u_x is a weak equivalence. By corollaries 2.3.16, 2.3.16 and 2.3.29, it is saturated by monomorphisms (ie stable under coproducts, pushouts, countable limits). Moreover it contains all representable presheaves so we can apply corollary 1.3.10.

Definition [Diagonal](#page-27-0)

Definition

A bisimplicial set is a presheaf over the product $\Delta \times \Delta$.

- For a bisimplicial set X, we write $X([m],[n]) = X_{m,n}$.
- For simplicial sets Y, Z, we set $(Y \boxtimes Z)_{m,n} = Y_m \times Z_n$.
- For a bisimplicial set X and a simplicial set K , write X^K for the simplicial set defined by

$$
(X^K)_m = \lim_{\substack{\leftarrow \\ \Delta^n \to K}} X_{m,n}
$$

So $\mathcal{K} \mapsto \mathcal{X}^{\mathcal{K}}$ is the extension by colimits of the functor $\Delta \to s$ Set sending $[n]$ to $X^{\Delta^n} = ([m] \mapsto X_{m,n})$.

• For a bisimplicial set X, write $diag(X)$ for the simplicial set defined by :

$$
diag(X)_n=X_{n,n}
$$

 \Rightarrow

Definition [Diagonal](#page-27-0)

Theorem 3.1.16.

If a morphism of bisimplicial sets $X \rightarrow Y$ is a levelwise weak homotopy equivalence (i.e. induces a weak homotopy equivalence $X^{\Delta^{m}}\to Y^{\Delta^{m}}$ for all $m > 0$), then the diagonal map

$$
diag(X) \rightarrow diag(Y)
$$

is a weak homotopy equivalence.

Sketch of proof.

Main point : use proposition 3.1.14 and the fact that $K \mapsto X^K$ is the extension by colimits of $[n] \mapsto X^{\Delta^n}$ to conclude that $X^K \to Y^K$ is a weak equivalence for any simplicial set K .
